

## Logically Complete

A set of logic gates (or logic operators),  $L$ , is **logically complete** if it can be used to build a logical circuit (or expression) that is **logically equivalent** to any arbitrary logical circuit (or expression).

For any arbitrary logical circuit,  $C$ , there is a logical circuit,  $C'$ , such that  $C \equiv C'$  and  $C'$  is constructed using **only** gates from  $L$ .

## Proving a Set of Gates is Logically Complete

- Approach (Reduction)

Give a canonical set of logically complete gates, say  $LCG$ , a different set of gates,  $K$ , could be proven to be logically complete by showing that  $\forall g \in LCG \exists g' \ni g \equiv g' \wedge g'$  only uses gates in  $K$ . This reduces the set  $K$  to a solved problem.

- Proving  $LCG$  is Logically Complete This is the hard part. Picking the first set to prove logically complete and then proving it.

- $\{\neg, \wedge, \vee\}$  Is Logically Complete

TBP:  $\forall K \in \{\text{LogicalExpression}\} \exists K' \ni K \equiv K' \wedge K'$  uses only operators from the set  $\{\neg, \wedge, \vee\}$ .

Given logical expression  $K$ :  $K$  has some number,  $n$ , logical variables and a truth table with  $2^n$  rows. Logic variables will be named  $x_i$  starting from  $0 \leq i < n$ .

Consider some row where  $K$  is 1.

Build a conjunction of all of the variables or their negation. For each column,  $i$ , if  $x_i$  is 1, include  $x_i$  in the conjunction; if  $x_i$  is 0, include its negation:

$$\bigwedge_{i=0}^{n-1} (x_i == 1) ? x_i : \overline{x_i}$$

With three logical variables and a  $K$  with four rows that are 1, four conjunctions are created in this next table.

$x_0$	$x_1$	$x_2$	$K$	$A$ $\overline{x_0}x_1x_2$	$B$ $\overline{x_0}x_1\overline{x_2}$	$C$ $x_0\overline{x_1}x_2$	$D$ $x_0x_1\overline{x_2}$	$K'$ $A \vee B \vee C \vee D$
0	0	0	0	0	0	0	0	0
0	0	1	1	1	0	0	0	1
0	1	0	0	0	0	0	0	0
0	1	1	1	0	1	0	0	1
1	0	0	0	0	0	0	0	0
1	0	1	1	0	0	1	0	1
1	1	0	0	0	0	0	0	0
1	1	1	1	0	0	0	1	1

Note that in the table  $K \equiv K'$  because the values are the same for every combination of input variables.

The  $K'$  column is generated by making a disjunct of all of the conjuncts built for the rows where  $K$  is 1.

Because each conjunct is 1 in only the row that was used to construct it, there is one conjunct with a 1 in each row where  $K$  is 1 and none with 1 in any row where  $K$  is 0. Joining them with a logical or creates a column with exactly as many 1 rows as there are conjuncts (none overlap) and in exactly the rows where  $K$  is 1. Thus the disjunct of the constructed conjuncts is the sought  $K'$ .

$\therefore$  We can build a conjunct for any row with a 1 in  $K$  using just  $\wedge$  and  $\neg$  operators. These conjuncts are combined in a disjunct with only the  $\vee$  operator. The resulting  $K'$  is logically equivalent to  $K$  by construction and uses only operators in the set  $\{\neg, \wedge, \vee\}$ .

$\therefore \forall K \in \{\text{LogicalExpression}\} \exists K' \ni K \equiv K' \wedge K'$  uses only operators from the set  $\{\neg, \wedge, \vee\}$ .

- Anything Else

- Make an And, an Or, and a Not
